Pneumatosis and submucosal esophageal gas in relation to bevacizumab. Pneumatosis intestinalis is the presence of free gas in the intestinal wall. It is commonly associated with gastrointestinal surgery or severe injury, and in most cases is self-limited. We present a patient who developed submucosal gas during treatment with bevacizumab, a monoclonal antibody targeting vascular endothelial growth factor-A, for metastatic colon cancer. The patient received bevacizumab concurrently with oxaliplatin/5-fluorouracil. The development of submucosal gas may be an adverse effect of bevacizumab in colorectal cancer."
